UNIVERSITÄT MANNHEIM

Database Technology
SQL Part 1

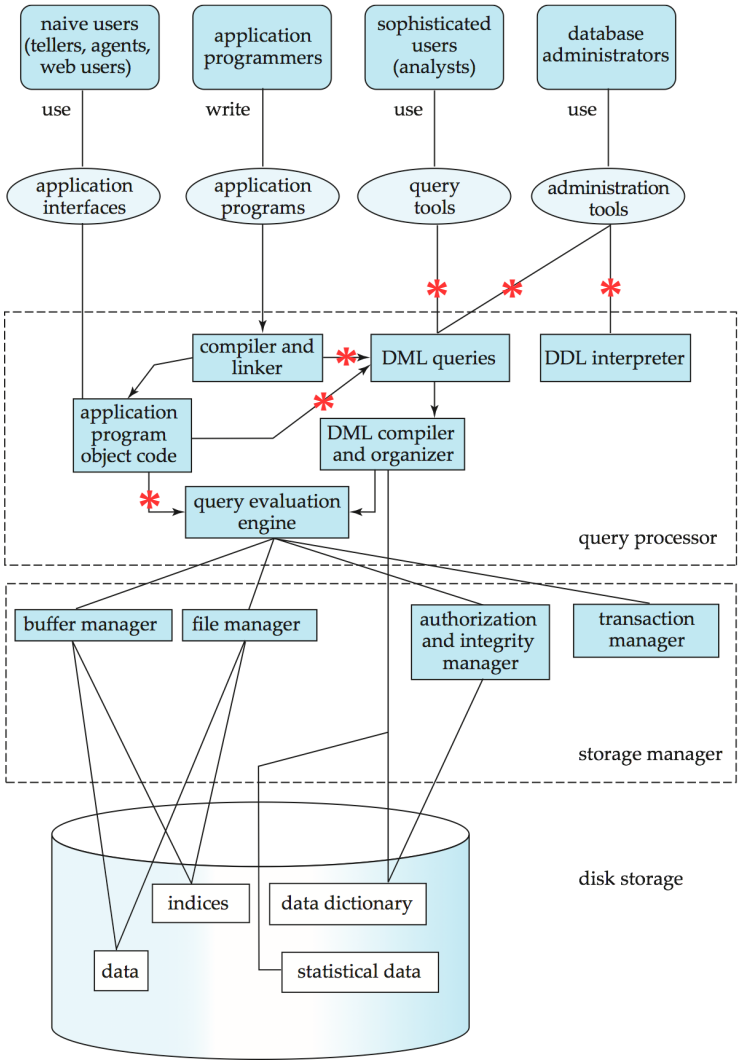
Heiko Paulheim

Outline

- Today
  - Overview of The SQL Query Language
  - Basic Query Structure
  - Set Operations
  - Join Operators
  - Null Values
  - Aggregate Functions
  - Nested Subqueries
- Next week
  - Data Definition
  - Data Types in SQL
  - Modifications of the database
  - Views
  - Integrity Constraints
  - Roles & Rights

Recap: Database Systems

- Users and applications interact with databases
  - By issuing *queries*
  - Data definition (DDL): defining, altering, deleting tables
  - Data manipulation (DML): reading from & writing to tables
- SQL is both a DDL and a DML
  - The language that most DBMS speak



History

- IBM SEQUEL language developed as part of System R project at the IBM San Jose Research Laboratory
  - *Structured English QUEry Language*
- Renamed Structured Query Language (SQL)
- ANSI and ISO standard SQL:
  - SQL-86
  - SQL-89
  - SQL-92
  - SQL:1999
  - SQL:2003

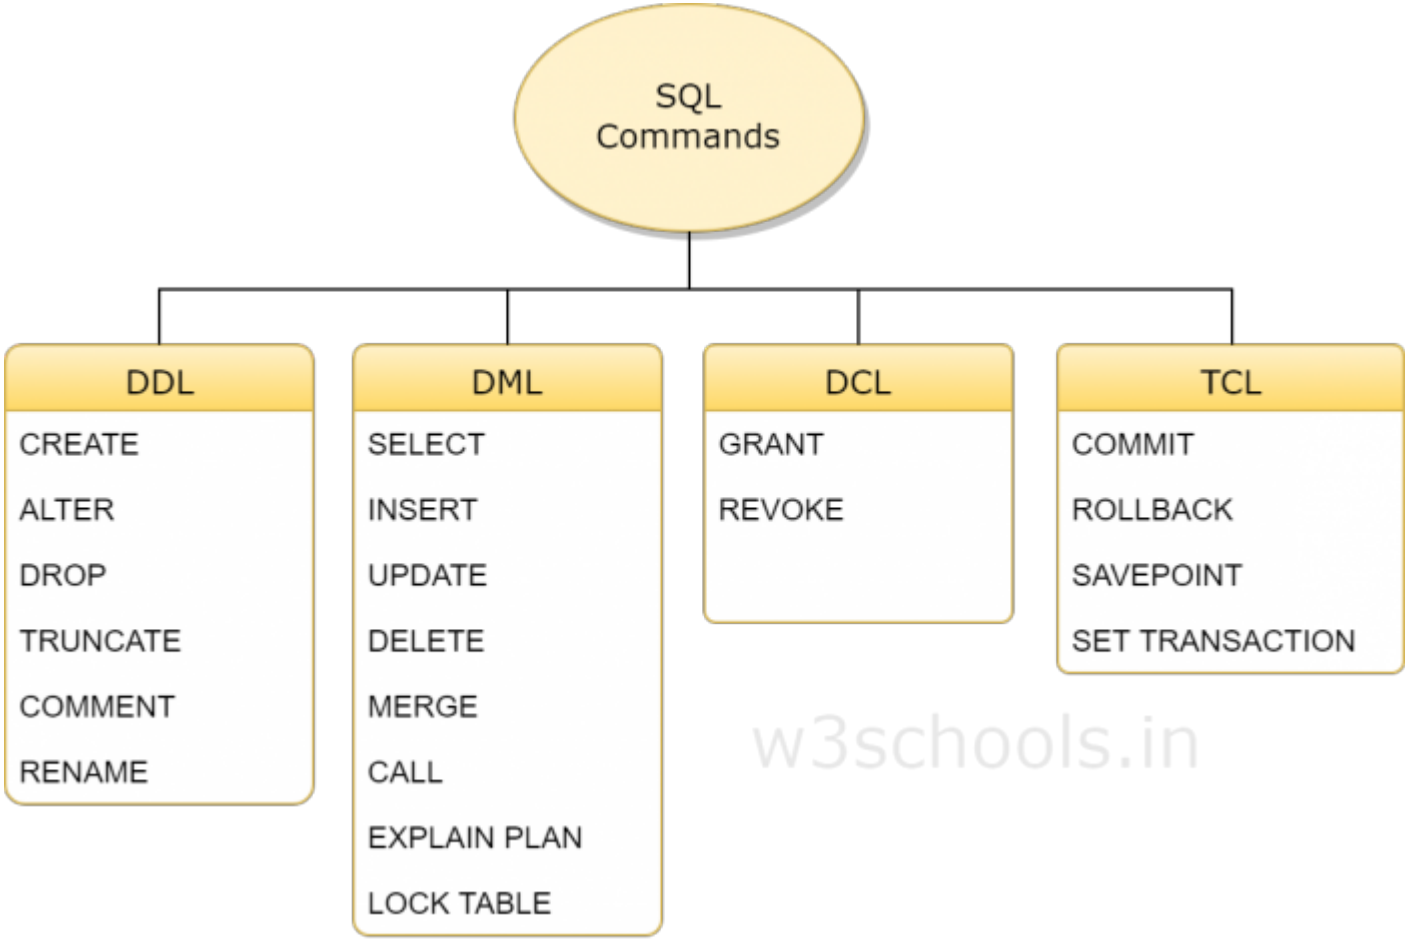
Naming became Y2K compliant! ;-)

ANSI
American National Standards Institute

ISO
International Organization for Standardization

- Commercial + free systems offer most, if not all, SQL-92 features
  - plus varying feature sets from later standards and special proprietary features
  - Not all examples here may work on your particular system!

Parts of SQL: The Big Picture



Source: https://www.w3schools.in/mysql/ddl-dml-dcl/

Reading Data

- The **select** clause lists the attributes desired in the result of a query
- Example: find the names of all instructors:

  select *name*
  from *instructor*

- In relational algebra:
  - Π_{name} (*instructor*)

A Note on Case Sensitivity

- SQL is completely case insensitive
  - **select = SELECT = SeLeCt**
- Also for names of relations and attributes
  - instructor = Instructor = INSTRUCTOR
  - name = NAME = nAmE
- Each relation / attribute can only exist once
  - Hence, two relations named *instructor* and *Instructor* would not be feasible
- Case sensitivity does *not* apply to values!
  - i.e., “Einstein” and “einstein” are different values!

Renaming Columns in a Select

- Columns can be renamed during selection
- **select** *name, salary* **as** *payment* **from** *instructor*

- In relational algebra
  - a composition of projection and renaming:

$$\rho_{payment \leftarrow salary}(\Pi_{name,salary}(instructor))$$

The Select Clause

- An asterisk in the select clause denotes “all attributes”

  select * **from** *instructor*

- An attribute can be a literal with no **from** clause, possibly renamed

  select ‘437’

  select ‘437’ **as** *FOO*

FOO
437

- An attribute can be a literal with **from** clause

  select *name*, ‘Instructor’ **as** *role* **from** *instructor*

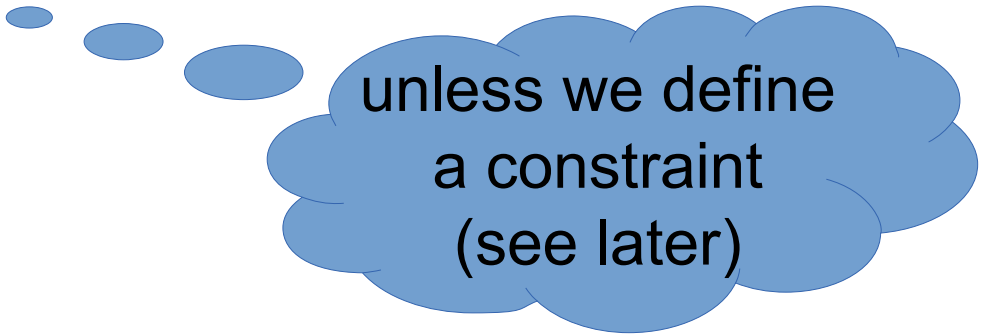
  union

  select *name*, ‘Student’ **as** *role* **from** *student*

name	role
Smith	Instructor
Einstein	Instructor
...	...
Johnson	Student
...	...

Duplicates

- Difference to relational algebra
  - Sets do not contain duplicates!
- SQL allows duplicates in relations as well as in query results



- To force the elimination of duplicates, insert the keyword **distinct** after select**.**
- Find the department names of all instructors, and remove duplicates

```
select distinct dept_name
        from instructor
```

Arithmetics in the Selection

- The **select** clause can contain arithmetic expressions involving the operation, +, –, ∗, and /, and operating on constants or attributes of tuples
  - Here, we leave relational algebra!

- The query

  select *ID, name, salary/12* **from** *instructor*

  would return a relation that is the same as the *instructor* relation, except that the value of the attribute *salary* is divided by 12
- Combined with renaming:
  - **select** *ID, name, salary/12* **as** *monthly_salary*

Reading Parts of a Relation

- So far, we have always read an entire relation
- Usually, we are interested only in a small portion
- The **where** clause restricts which parts of the table to read

- To find all instructors in Comp. Sci. dept

```
select name
  from instructor
  where dept_name = ‘Comp. Sci.'
```

- In relational algebra: combination of selection and projection

$$\pi_{\text{name}}(\sigma_{\text{dept\_name = ‘Comp. Sci.’}}(r))$$

Reading Parts of a Relation

- Comparison results can be combined using the logical connectives **and, or,** and **not**

  select *name*
  from *instructor*
  where *dept_name* = *'*Comp. Sci.' **and** *salary* > 90000

  $\pi_{name}(\sigma_{dept\_name = \text{'Comp. Sci.'} \wedge salary>90000}(r))$

- Can be combined with results of arithmetic expressions

  select *name, salary/12* ***as*** *monthly_salary*
  from *instructor*
  where *dept_name* = *'*Comp. Sci.' **and** *monthly_salary* > 7500

Searching in Texts

- So far, we have handled exact equality in selections
- Sometimes, we want to search differently
  - All books that contain “database”
  - All authors starting with “S”
  - …

- In SQL: comparing with **like** and two special characters:
  - _ = any arbitrary character
  - % = any number of arbitrary characters
  - masking with backslash

    select … where *title* **like** ‘%database%’

    select … **where** *author* **like** ‘S%’

    select … **where** *amount* **like** *‘100\%’*

most SQL engines don’t check types

Reading Data from Multiple Tables

- Example: find all instructors and the courses they teach
- **select** $*$ **from** *instructor, teaches*
  - this generates the *cartesian product*, i.e., instructor x teaches
  - result: generates every possible instructor – teaches pair, with all attributes from both relations
- Common attributes (e.g., *ID*), the attributes in the resulting table are renamed using the relation name
  - e.g., *instructor.ID, teaches.ID*

but is that useful?

- Relational algebra notation:
  - $\rho_{instructor.ID \leftarrow ID}(instructor)$ x $\rho_{teaches.ID \leftarrow ID}$(teaches)

Cartesian Product

instructor

Cartesian Product of a Table with Itself

- Find the names of all instructors who have a higher salary than some instructor in 'Comp. Sci'.
  - We need the same table twice
  - So, we have to use it under different names

    select distinct *T.name*
    from *instructor* **as** *T, instructor* **as** *S*
    where *T.salary* > *S.salary* **and** *S.dept_name* = *'Comp. Sci.'*

    $\pi_{T,name}(\sigma_{T.salary>S.salary \wedge S.dept\_name='Comp.\ Sci.'}(\rho_T(\text{instructor}) \times \rho_S(\text{instructor})))$

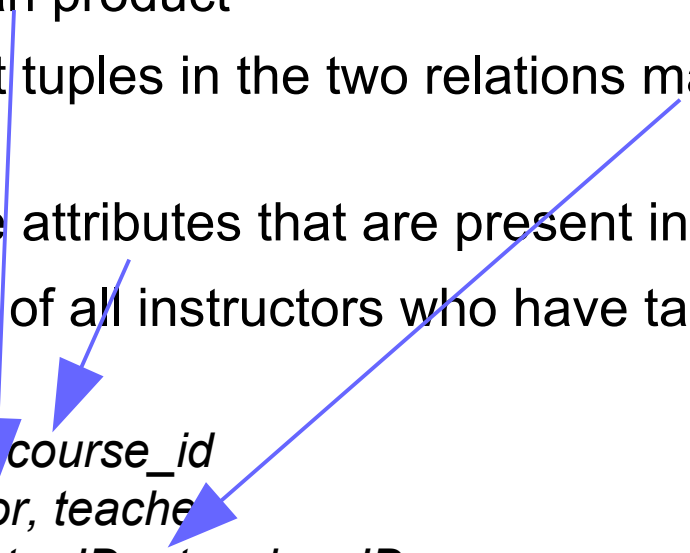
- What happens if we omit the **distinct** here?

Join Operations

- **Join operations**
  - take two relations
  - return as new relation as their result
- A join operation
  - is a Cartesian product
  - requires that tuples in the two relations match (under some condition)
  - specifies the attributes that are present in the result of the join
- The join operations are typically used as subquery expressions in the **from** clause

Join Operations

- Recap: We have already seen a form of joins:
- A join operation
  - is a Cartesian product
  - requires that tuples in the two relations match (under some condition)
  - specifies the attributes that are present in the result of the join
- Find the names of all instructors who have taught some course and the course_id



select *name, course_id*
from *instructor, teaches*
where *instructor.ID = teaches.ID*

Outer Joins

- Consider the two relations below
- Desired:
  - List all courses with their prerequisites
  - Note: course CS-315 has no prerequisites

course_id	*title*	*dept_name*	*credits*
BIO-301	Genetics	Biology	4
CS-190	Game Design	Comp. Sci.	4
CS-315	Robotics	Comp. Sci.	3

course_id	*prereq_id*
BIO-301	BIO-101
CS-190	CS-101
CS-347	CS-101

Outer Joins

- List all courses with their prerequisites

  select *C.course_id, C.title, C.credits, C.dept_name, P.course_id*
  from *course* **as** *C, prereq* **as** *P*
  where *C.course_id = P.course_id*

course_id	*title*	*dept_name*	*credits*
BIO-301	Genetics	Biology	4
CS-190	Game Design	Comp. Sci.	4
CS-315	Robotics	Comp. Sci.	3

course_id	*prereq_id*
BIO-301	BIO-101
CS-190	CS-101
CS-347	CS-101

C.course_id	C.title	C.credits	C.dept_name	P.course_id
BIO-301	Genetics	4	Biology	BIO-101
CS-190	Game Design	4	Comp. Sci.	CS-101

Outer Joins

- List all courses with their prerequisites

  select *C.course_id, C.title, C.credits, C.dept_name, P.prereq_id*
  from *course* **as** *C* **left outer join** *prereq* **as** *P*
  on *C.course_id = P.course_id*

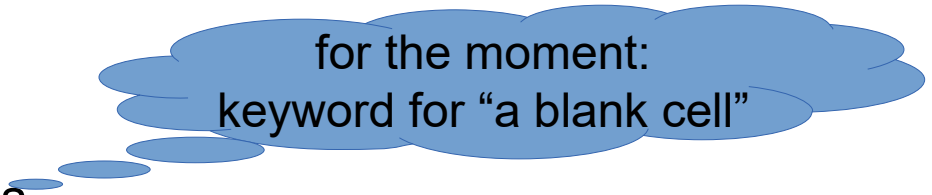
course_id	*title*	*dept_name*	*credits*
BIO-301	Genetics	Biology	4
CS-190	Game Design	Comp. Sci.	4
CS-315	Robotics	Comp. Sci.	3

course_id	*prereq_id*
BIO-301	BIO-101
CS-190	CS-101
CS-347	CS-101

C.course_id	C.title	C.credits	C.dept_name	P.prereq_id
BIO-301	Genetics	4	Biology	BIO-101
CS-190	Game Design	4	Comp. Sci.	CS-101
CS-315	Robotics	3	Comp. Sci.	**null**

Join Operations

- **Join type** – defines how tuples in each relation that do not match any tuple in the other relation (based on the join condition) are treated
  - **inner join**: ignore
  - **outer join**: fill with **null** values



- **Join condition** – defines which tuples in the two relations match, and what attributes are present in the result of the join
  - explicit: **on** clause
  - implicit: **natural** keyword

Join types
inner join
left outer join
right outer join
full outer join

Join Conditions
natural
on <predicate>
using $(A_1, A_1, \ldots, A_n)$

Outer Joins

- List all courses with their prerequisites

  select *C.course_id, C.title, C.credits, C.dept_name, P.prereq_id*
  from *course* **as** *C* **right outer join** *prereq* **as** *P*
  on *C.course_id = P.course_id*

course_id	*title*	*dept_name*	*credits*
BIO-301	Genetics	Biology	4
CS-190	Game Design	Comp. Sci.	4
CS-315	Robotics	Comp. Sci.	3

course_id	*prereq_id*
BIO-301	BIO-101
CS-190	CS-101
CS-347	CS-101

C.course_id	C.title	C.credits	C.dept_name	P.prereq_id
BIO-301	Genetics	4	Biology	BIO-101
CS-190	Game Design	4	Comp. Sci.	CS-101
CS-347	**null**	**null**	**null**	CS-101

Outer Joins

- List all courses with their prerequisites

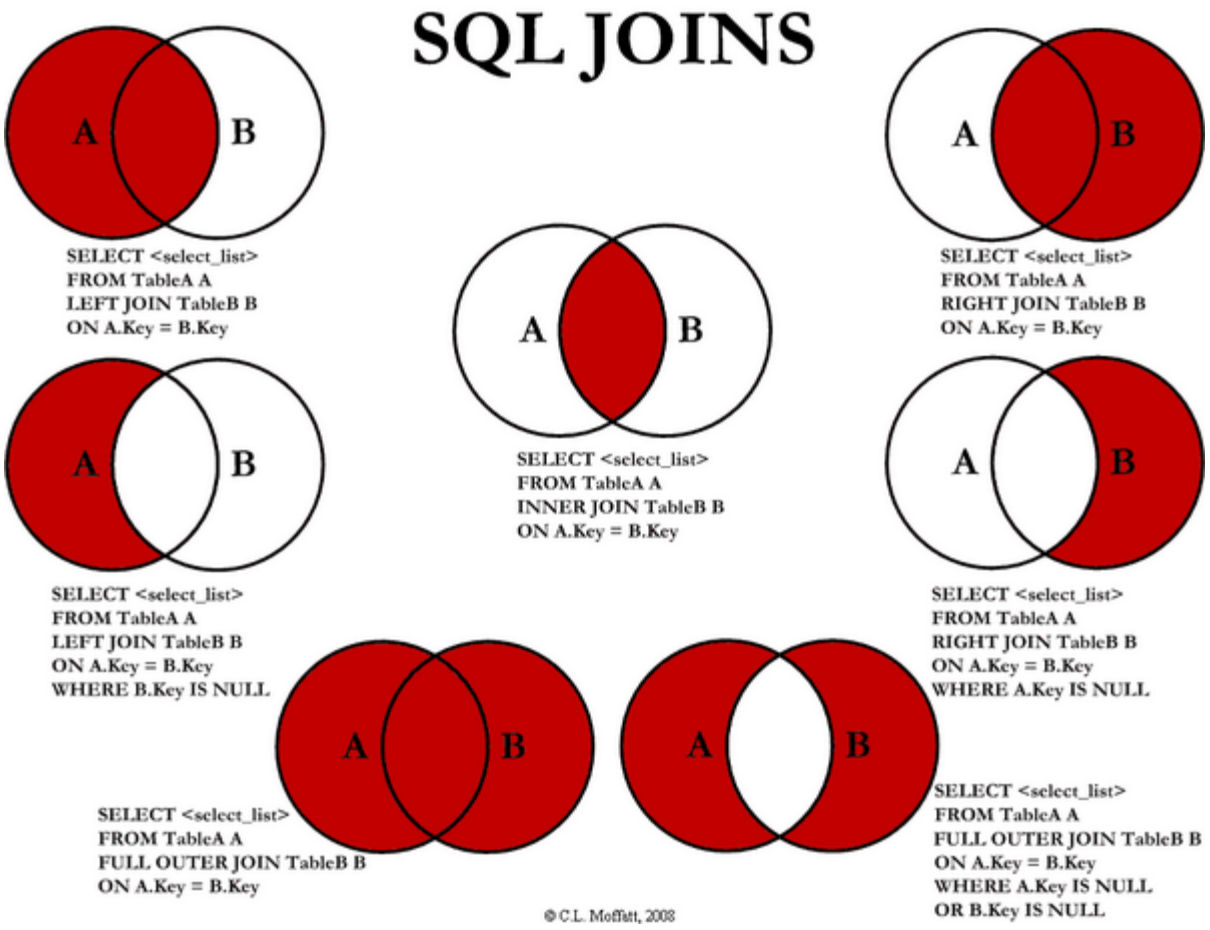
  select *C.course_id, C.title, C.credits, C.dept_name, P.prereq_id*
  from *course* **as** *C* **full outer join** *prereq* **as** *P*
  on *C.course_id = P.course_id*

course_id	*title*	*dept_name*	*credits*
BIO-301	Genetics	Biology	4
CS-190	Game Design	Comp. Sci.	4
CS-315	Robotics	Comp. Sci.	3

course_id	*prereq_id*
BIO-301	BIO-101
CS-190	CS-101
CS-347	CS-101

C.course_id	C.title	C.credits	C.dept_name	P.prereq_id
BIO-301	Genetics	4	Biology	BIO-101
CS-190	Game Design	4	Comp. Sci.	CS-101
CS-347	**null**	**null**	**null**	CS-101
CS-315	Robotics	3	Comp. Sci.	**null**

Join Types at a Glance



https://www.codeproject.com/Articles/33052/Visual-Representation-of-SQL-Joins

Ordering Results

- Recap: Relational Algebra works on sets
  - i.e., it does not have orderings

- For database applications, ordering is often useful, e.g.,
  - list students ordered by names

    select *id,name*
    from *student*
    order by *name*

  - list instructors ordered by department first, then by name

    select *id,name,dept_name*
    from *instructor*
    order by *dept_name, name*

Limiting Results

- Find the three lecturers with the highest salaries

```
select id,name,salary
from   instructor
order by salary desc
limit 3;
```

- *Note:* the **desc** keyword creates a descending ordering
- **asc** also exists and creates an ascending ordering
  - also the default when not specifiying the direction

Paging with LIMIT and OFFSET

- Applications, e.g., Web applications, often offer a *paged* view
- Example:
  - Display student list on pages of 100 students
  - with navigation (next page, previous page)

```
select id,name
from   student
order by name
limit 100
offset 100;
```

- **offset** 100 means: skip the first 100 entries
  - i.e., this query would create the second page
- *Note:* offset should only be used with **order by**
  - otherwise, the results are not deterministic

Set Operations

- All courses that are offered in HWS 2017 *and* FSS 2018

  (**select** *course_id* **from** *section* **where** *sem* = 'HWS' **and** *year* = 2017)
  intersect
  (**select** *course_id* **from** *section* **where** *sem* = 'FSS' **and** *year* = 2018)

  $\pi_{course\_id}(\sigma_{sem='HWS' \wedge year=2017}(section)) \cap \pi_{course\_id}(\sigma_{sem='FSS' \wedge year=2018}(section))$

- All courses that are offered in HWS 2017 *but not in* FSS 2018

  (**select** *course_id* **from** *section* **where** *sem* = 'HWS' **and** *year* = 2017)
  except
  (**select** *course_id* **from** *section* **where** *sem* = 'FSS' **and** *year* = 2018)

  $\pi_{course\_id}(\sigma_{sem='HWS' \wedge year=2017}(section)) - \pi_{course\_id}(\sigma_{sem='FSS' \wedge year=2018}(section))$

Set Operations

- All courses that are offered in HWS 2017 *or* FSS 2018

  (**select** *course_id* **from** *section* **where** *sem* = 'HWS' **and** *year* = 2017)
  union
  (**select** *course_id* **from** *section* **where** *sem* = 'FSS' **and** *year* = 2018)

  $\pi_{course\_id}(\sigma_{sem='HWS' \wedge year=2017}(section)) \cup \pi_{course\_id}(\sigma_{sem='FSS' \wedge year=2018}(section))$

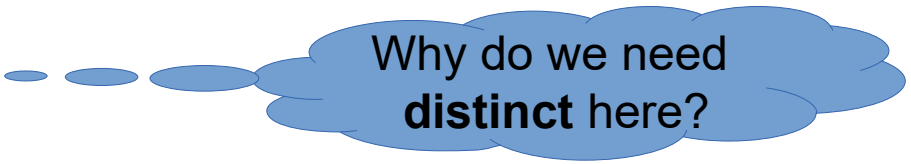
- Alternative solution

  (**select** course_id **from** section **where**
  ((*sem* = 'HWS' **and** *year* = 2017) **or** (*sem* = 'FSS' **and** *year* = 2018))

  $\pi_{course\_id}(\sigma_{(sem='HWS' \wedge year=2017) \vee (sem='FSS' \wedge year=2018))}(section))$

Aggregate Functions – Examples

- Find the average salary of instructors in the Computer Science department
  - **select avg** (*salary*)
    from *instructor*
    where *dept_name*= 'Comp. Sci.';
- Find the number of tuples in the *course* relation
  - **select count** (*)
    from *course*;
- Find the total number of instructors who teach a course in the Spring 2010 semester
  - **select count** (**distinct** *ID*)
    from *teaches*
    where *semester* = 'Spring' **and** *year* = 2010;



Aggregate Functions with Group By

- Find the average salary of instructors in each department
  - **select** *dept_name*, **avg** (*salary*) **as** *avg_salary*
    from *instructor*
    group by *dept_name*;

ID	*name*	*dept_name*	*salary*
76766	Crick	Biology	72000
45565	Katz	Comp. Sci.	75000
10101	Srinivasan	Comp. Sci.	65000
83821	Brandt	Comp. Sci.	92000
98345	Kim	Elec. Eng.	80000
12121	Wu	Finance	90000
76543	Singh	Finance	80000
32343	El Said	History	60000
58583	Califieri	History	62000
15151	Mozart	Music	40000
33456	Gold	Physics	87000
22222	Einstein	Physics	95000

dept_name	*avg_salary*
Biology	72000
Comp. Sci.	77333
Elec. Eng.	80000
Finance	85000
History	61000
Music	40000
Physics	91000

Aggregate Functions with Group By

- Attributes in **select** clause outside of aggregate functions must appear in **group by** list

/* erroneous query */
select *dept_name*, *ID*, **avg** (*salary*)
from *instructor*
group by *dept_name*;

ID	*name*	*dept_name*	*salary*
76766	Crick	Biology	72000
45565	Katz	Comp. Sci.	75000
10101	Srinivasan	Comp. Sci.	65000
83821	Brandt	Comp. Sci.	92000
98345	Kim	Elec. Eng.	80000
12121	Wu	Finance	90000
76543	Singh	Finance	80000
32343	El Said	History	60000
58583	Califieri	History	62000
15151	Mozart	Music	40000

Conditions on Aggregate Values

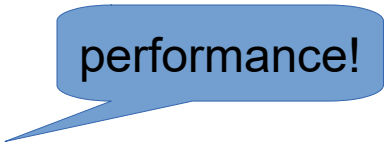
- Find the names and average salaries of all departments whose average salary is greater than 42000
  - **select** *dept_name*, **avg** (*salary*) **as** *avg_salary*
    from *instructor*
    group by *dept_name*
    where *avg_salary* > 42000;

- Problem:
  - Aggregation is performed *after* selection and projection
  - Hence, the variable *avg_salary* is not available when the **where** clause is evaluated

→ The above query will not work

Conditions on Aggregate Values

- Find the names and average salaries of all departments whose average salary is greater than 42000
  - **select** *dept_name*, **avg** (*salary*) **as** *avg_salary*
    from *instructor*
    group by *dept_name*
    having *avg_salary* > 42000;



- The **having** clause is evaluated *after* the aggregation
- Hence, it is different from the **where** clause

- Rule of thumb
  - Conditions on aggregate values can only be defined using **having**

NULL Values

- *null* signifies an unknown value or that a value does not exist
- It is possible for tuples to have a null value, denoted by *null*, for some of their attributes
  - can be forbidden by a **not null** constraint
  - keys can never be null!
- The result of any arithmetic expression involving *null* is *null*
- Example: 5 + *null* returns null
- The predicate **is null** can be used to check for null values
- Example: Find all instructors whose salary is null.

select *name*
from *instructor*
where *salary* **is null**

NULL Values and Three Valued Logic

- Three values – *true*, *false*, *unknown*
- Any comparison with *null* returns *unknown*
  - Example*: 5 < null or null <> null or null = null*
- Three-valued logic using the value *unknown*:
  - OR: (*unknown* **or** *true*) = *true*,
    (*unknown* **or** *false*) = *unknown*
    (*unknown* **or** *unknown)* = *unknown*
  - AND: *(true* **and** *unknown)* = *unknown,*
    (false **and** *unknown)* = *false,*
    (unknown **and** *unknown)* = *unknown*
  - NOT*: (***not** *unknown)* = *unknown*
- "*P* **is unknown**" evaluates to true if predicate *P* evaluates to *unknown*
- Result of **where** clause predicate is treated as *false* if it evaluates to *unknown*

Aggregates and NULL Values

- Total all salaries

  select sum (*salary*)
  from *instructor*

  – Above statement ignores null amounts

  – Result is *null* if there is no non-null amount

- All aggregate operations except **count(*)** ignore tuples with null values on the aggregated attributes
- What if collection has only null values?
  – count returns 0
  – all other aggregates return null

ID	*name*	*dept_name*	*salary*
76766	Crick	Biology	72000

22222	Einstein	Physics	null

Subqueries

- SQL provides a mechanism for the nesting of subqueries. A **subquery** is a **select-from-where** expression that is nested within another query.
- The nesting can be done in the following SQL query

select A_1, A_2, ..., A_n
from r_1, r_2, ..., r_m
where P

as follows:

- A_i can be replaced be a subquery that generates a single value
- r_i can be replaced by any valid subquery
- P can be replaced with an expression of the form:

B <operation> (subquery)

Where B is an attribute and <operation> to be defined later

Subqueries in the WHERE Clause

- A common use of subqueries is to perform tests:
  - for set membership
  - for set comparisons
  - for set cardinality

Test for Set Membership

- Find courses offered this term by lectures from the biology department

```
select distinct course_id
from teaches
where semester = 'Spring' and year= 2022 and
   ID in (select ID from instructor where dept_name = 'Biology');
```

- Find courses offered this term before 9 am or after 5 pm

```
select distinct course_id
from section
where semester = 'Spring' and year= 2022 and
   time_slot_id not in (select time_slot_id from time_slot
                        where end_time >= 9 and start_time <= 17);
```

Test for Set Membership

- Find the total number of (distinct) courses offered by instructors in the biology department

```
select count(distinct course_id )
from teaches
where semester = 'Spring' and year= 2022 and
   ID in (select ID from instructor where dept_name = 'Biology');
```

- Note: in all of those cases,
  other (sometimes simpler) solutions are possible
  - In SQL, there are often different ways to solve a problem
  - A question of personal taste
  - But also: a question of performance...

Test for Set Membership

- Find the total number of (distinct) courses offered by instructors in the biology department

```
select count(distinct course_id )
from teaches
where semester = 'Spring' and year= 2022 and
   ID in (select ID from instructor where dept_name = 'Biology');
```

creates a temporary table

- vs.

```
select count (distinct course_id)
from teaches, instructor
where teaches.ID = instructor.ID and instructor.department = 'Biology';
```

computes Cartesian product

Set Comparison with SOME

- Find names of instructors with salary greater than that of some (at least one) instructor in the Biology department

```
select distinct T.name
from instructor as T, instructor as S
where T.salary > S.salary and S.dept name = 'Biology';
```

- Same query using > **some** clause

```
select name
from instructor
where salary > some (select salary
                     from instructor
                     where dept name = 'Biology');
```

Set Comparison with ALL

- Find names of instructors with salary greater than that of all instructors in the Biology department

```
select name
from instructor
where salary > all (select salary
                    from instructor
                    where dept name = 'Biology');
```

- Note: we could also achieve this with MIN and MAX aggregates in the subqueries

Definition: Comparisons with SOME

- F <comp> **some** $r \Leftrightarrow \exists\, t \in r$ such that (F <comp> t)
  Where <comp> can be: $<,\ \leq,\ >,\ =,\ \neq$

(5 < **some** | 0 | 5 | 6 |) = true (read: 5 < some tuple in the relation)

(5 < **some** | 0 | 5 |) = false

(5 = **some** | 0 | 5 |) = true

(5 ≠ **some** | 0 | 5 |) = true (since 0 ≠ 5)

(= **some**) ≡ **in**
However, (≠ **some**) ≢ **not in**

Definition: Comparisons with ALL

- F <comp> **all** $r \Leftrightarrow \forall\ t \in r$ (F <comp> *t)*

(5 < **all** | 0, 5, 6 |) = false

(5 < **all** | 6, 10 |) = true

(5 = **all** | 4, 5 |) = false

(5 ≠ **all** | 4, 6 |) = true (since 5 ≠ 4 and 5 ≠ 6)

(≠ **all**) ≡ **not in**
However, (= **all**) ≢ **in**

Existential Quantification in Subqueries

- Select all courses offered this year which are taken by at least one student
  - **select** *course_id*
    from *section*
    where *semester* = 'Spring' **and** *year* = 2022 **and**
    exists (**select** *
    from *takes*
    where *takes.course_id = section.course_id*
    and *takes.sec_id = section.sec_id*
    and *takes.semester = section.semester*);

- The **exists** construct returns the value **true** if the result of the subquery is not empty
  - **exists** $r \Leftrightarrow r \neq \emptyset$
  - **not exists** $r \Leftrightarrow r = \emptyset$

Subqueries with NOT EXISTS

- Find all students who have taken all courses offered in the Biology department

```
select distinct S.ID, S.name
from student as S
where not exists ( (select course_id
                    from course
                    where dept_name = 'Biology')
                   except
                    (select T.course_id
                     from takes as T
                     where S.ID = T.ID));
```

  - First nested query lists all courses offered in Biology
  - Second nested query lists all courses a particular student took

- Note that $X - Y = \emptyset \Leftrightarrow X \subseteq Y$
- Note: Cannot write this query using **= all** and its variants

Test for Duplicate Tuples

- Find all courses that were offered at most once in 2009

```
select T.course_id
from course as T
where unique (select R.course_id
              from section as R
              where T.course_id= R.course_id
                    and R.year = 2009);
```

- The **unique** construct evaluates to “true” if a given subquery contains no duplicates
- With **not unique**, we could query for courses that were offered more than once

Subqueries in the FROM Clause

- So far, we have considered subqueries in the **where** clause
- Find the average instructors' salaries of those departments where the average salary is greater than $42,000."

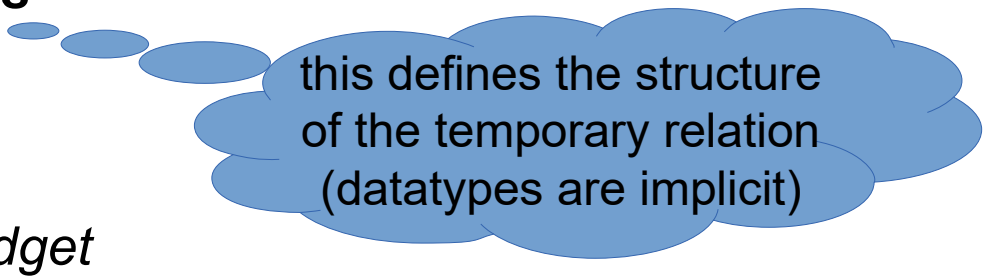
```
select dept_name, avg_salary
from
        (select dept_name, avg (salary) as avg_salary
                        from instructor
                group by dept_name)
where avg_salary > 42000;
```

- Note that we do not need to use the **having** clause
  - why?

Creating Temporary Relations Using WITH

- Find all departments with the maximum budget

```
with max_budget (value) as
        (select max(budget)
         from department)
select department.name
from department, max_budget
where department.budget = max_budget.value;
```



- The **with** clause provides a way of defining a temporary relation whose definition is available only to the query in which the **with** clause occurs

Creating Temporary Relations Using WITH

- A more complex example involving two temporary relations:
  - Find all departments where the total salary is greater than the average of the total salary at all departments

```
with
dept _total (dept_name, value) as
        (select dept_name, sum(salary)
         from instructor
         group by dept_name),
dept_total_avg(value) as
       (select avg(value)
       from dept_total)
select dept_name
from dept_total, dept_total_avg
where dept_total.value > dept_total_avg.value;
```

Scalar Subqueries in the SELECT Part

- List all departments along with the number of instructors in each department

```
select dept_name,
        (select count(*)
          from instructor
         where
           department.dept_name = instructor.dept_name)
        as num_instructors
from department;
```

- Scalar subqueries return a single result
  - More specifically: a single *tuple*
- Runtime error if subquery returns more than one result tuple

Summary of Subqueries

- SELECT queries are the most often used part of SQL
- Their basic structure is simple, but subqueries are a powerful means to make them quite expressive

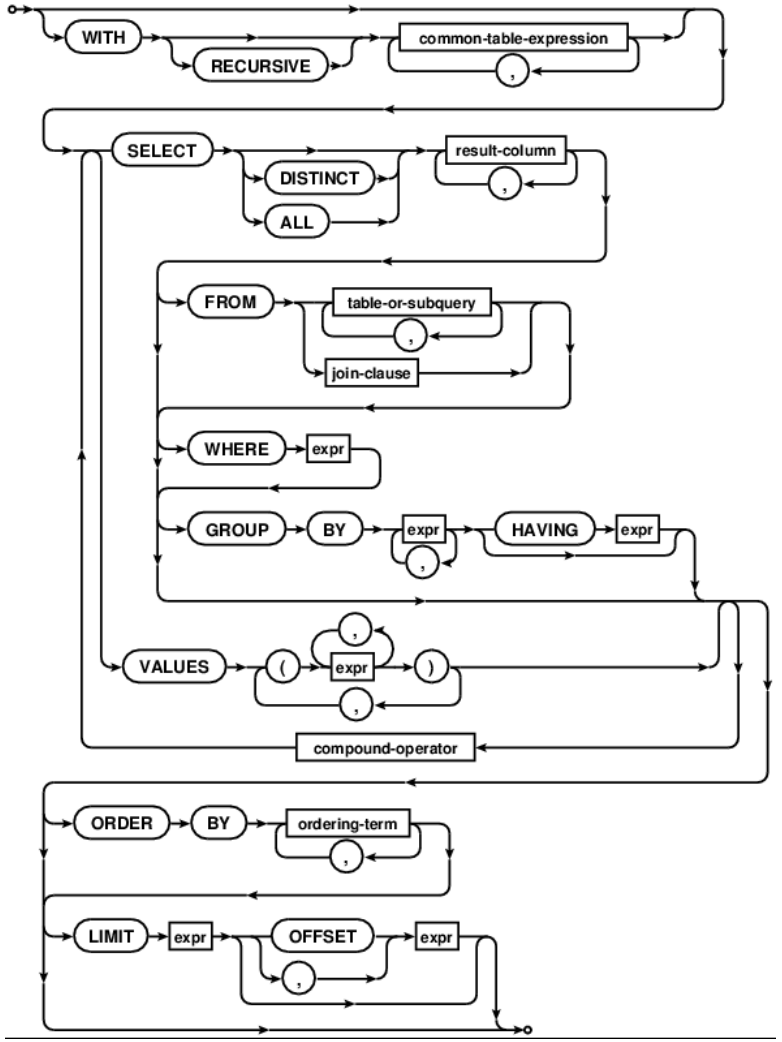
  select A_1, A_2, ..., A_n

  from r_1, r_2, ..., r_m

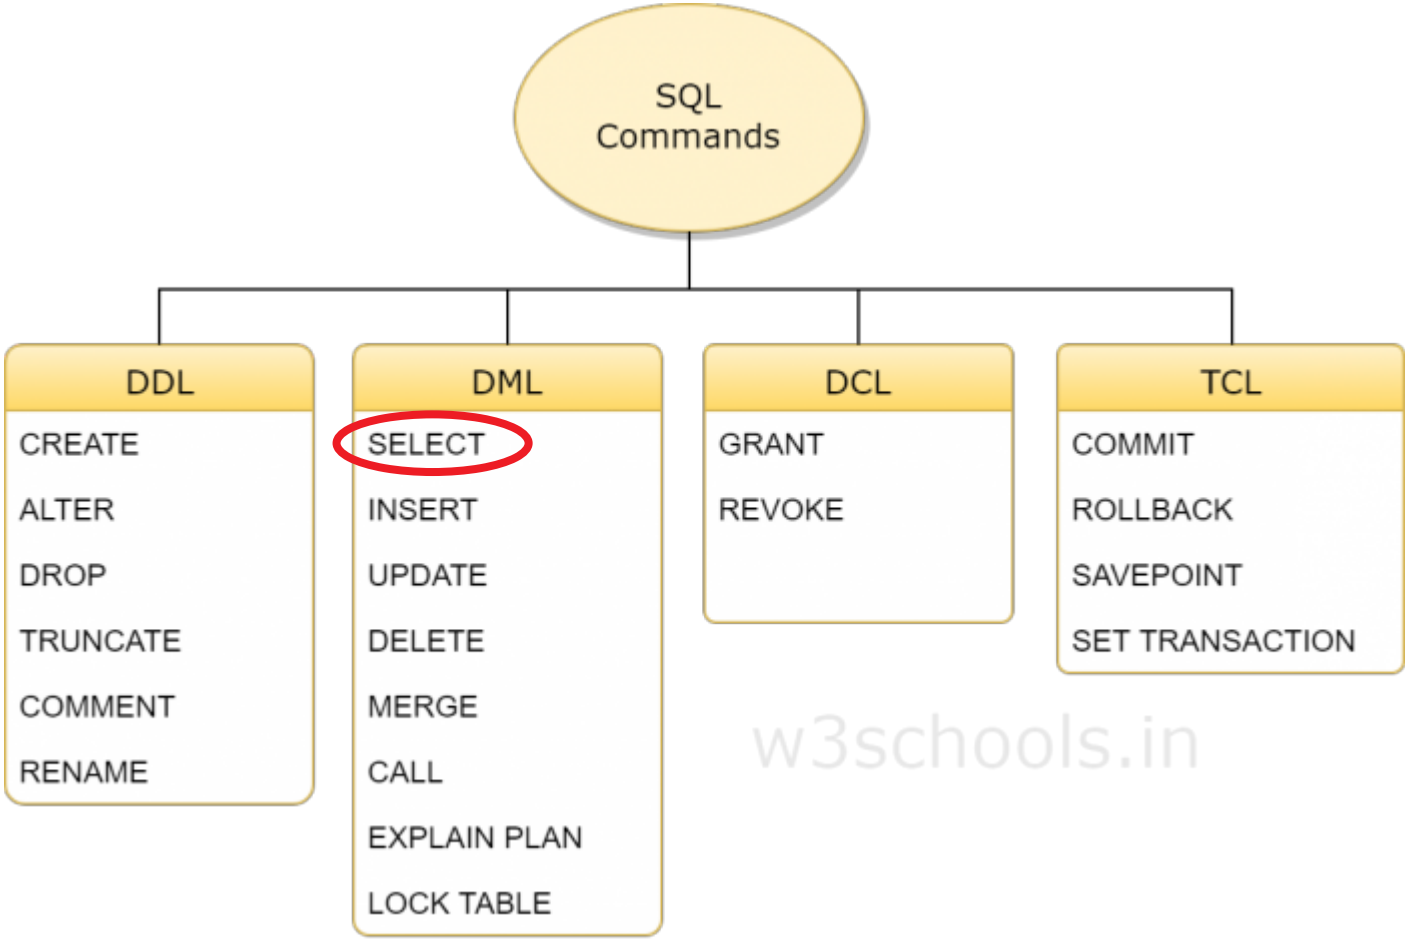
  where P
- Subqueries in **select** part (A_1, A_2, ..., A_n)
  - Scalar subqueries (single values, like aggregates)
- Subqueries in **from** part (r_1, r_2, ..., r_m)
  - Temporary relations (can also be defined using **with**)
- Subqueries in **where** part (P)
  - Set comparisons, empty sets, test for duplicates
  - Universal and existential quantification

Summary: SQL SELECT at a Glance

- The tool support of SQL varies
- what we have covered here is standard SQL
  - Supported by *most* tools



Recap: The Big Picture



Source: https://www.w3schools.in/mysql/ddl-dml-dcl/

Summary and Take Aways

- SQL is a standarized language for relational databases
  - DML: Data Manipulation Language

- DML
  - Read data from tables using SELECT

- Coming Up:
  - Writing data to tables
  - Creating and changing tables
  - Rights & Roles
  - …
