Web Data Integration

Schema Mapping and Data Translation
The Data Integration Process

1. Data Collection / Extraction
2. Schema Mapping
3. Identity Resolution
4. Data Quality Assessment
5. Data Fusion
Outline

1. Two Basic Integration Situations
2. Types of Correspondences
3. Schema Integration
4. Data Translation
5. Schema Matching
6. Schema Heterogeneity on the Web
Goal: Translate data from a set of source schemata into a given target schema.

- Top-down integration situation
- Triggered by concrete information need (= target schema)
The Schema Mapping Process

1. Find Correspondences
   - All correspondences together form the logical mapping

2. Translate Data
   - Translation Queries (Translation Program)

Source Schema

Source Data

Logical Mapping

Given Target Schema

Materialized Data in Target Schema
Basic Integration Situation 2: Schema Integration

Goal: Create a new integrated schema that can represent all data from a given set of source schemata.

- Bottom-up integration situation
- Triggered by the goal to fulfill different information needs based on data from all sources.
2. Correspondences

A correspondence relates a set of elements in a schema S to a set of elements in schema T.

- **Mapping** = Set of all correspondences that relate S and T
- Correspondences are easier to specify than transformation queries
  - domain expert does not need technical knowledge about query language
  - specification can be supported by user interfaces (mapping editors)
  - step-by-step process with separate local decisions
- Correspondences can be annotated with transformation functions
  - normalize units of measurement (€ to US$, cm and km to meters)
  - calculate or aggregate values (salary * 12 = yearly salary)
  - cast attribute data types (integer to real)
  - translate values using a translation table (area code to city name)
Types of Correspondences

- One-to-One Correspondences
  - Movie.title → Item.name
  - Product.rating → Item.classification
  - Movie ≡ Film (equivalence: Same semantic intention)
  - Athlete ⊆ Person (inclusion: All athletes are also persons)

- One-to-Many Correspondences
  - Person.Name → split() → FirstName (Token 1)
    → Surname (Token 2)

- Many-to-One Correspondences
  - Product.basePrice * (1 + Location.taxRate) → Item.price

- Higher-Order Correspondences
  - relate different types of data model elements
  - for example: Relations (classes) and attributes, see next slide
Examples of Higher-Order Correspondences

Relation-to-Value Correspondences

Value-to-Relation Correspondences

Man
Firstname
Surname
Woman

Surname
Types of Schema Heterogeneity that can be Captured

- Naming of
  - Relations
  - Attributes
- Normalized vs. Denormalized
- Nesting vs. Foreign Keys
- Alternative Modelling
  - Relation vs. Value
  - Relation vs. Attribute
  - Attribute vs. Value

\[ 1:1, 1:n, n:1 \]

Correspondences

\[ \text{Higher-order Correspondences} \]
Defining Correspondences
Discovering Correspondences

**Schema Matching:** Automatically or semi-automatically discover correspondences between schemata.

- Various schema matching methods exist (we will cover them later)
- Automatically finding a complete high-quality mapping is not possible in most real-world cases. Halevy: „It’s plain hard.“ :-(
- In practice, schema matching is often used to create candidate correspondences that are verified by human experts afterwards
- Realistic goals
  1. use matching to reduce the effort required from domain experts or
  2. be prepared to tolerate some noise in the generated mapping
3. Schema Integration

Create a new integrated schema that can represent all data from a given set of source schemata.

- **Goals:**
  - **Completeness:** All elements of the source schemata should be covered
  - **Correctness:** All data should be represented semantically correct
    - cardinalities, integrity constraints, …
  - **Minimality:** The integrated schema should be minimal in respect to the number of relations and attributes
    - redundancy-free
  - **Understandability:** The schema should be easy to understand
Example: Two Schemata about Films

Having a different focus and a different level of detail

- **Schema 1**: Who are the directors of a movie?
- **Schema 2**: What are the details about the studio in which the movie was shot?

- **Goals**:
  1. Completeness
  2. Correctness
  3. Minimality
  4. Understandability
Schema Integration: Rules of Thumb

1. Merge all tables with equivalent tables in other schema (Film, Movie)
2. Add all tables without equivalent tables (Director, Directs, Studio)
3. Add relationships with highest cardinality in order to keep expressivity (keep Directs)
Example of a Schema Integration Method

- Spaccapietra, et al.: Model Independent Assertions for Integration of Heterogeneous Schemas. VLDB 1992

- Input
  1. Two source schemata in Generic Data Model
     • classes, attributes, and relationships
     • similar to Entity Relationship Model
  2. Correspondence Assertions
     • correspondences between classes, attributes, and relationships
     • correspondences between paths of relationships

- Output: Integrated Schema
Integration Rules

Include into the target schema S:

1. Equivalent classes and merge their attribute sets
   - Pick class / attribute names of your choice for equivalent classes / attributes

2. Classes with their attributes that are not part of any class-class correspondence (classes without direct equivalent)

3. Direct relationships between equivalent classes
   - If \( A \equiv A', B \equiv B', A-B \equiv A'-B' \) then include \( A-B \)

4. Paths between equivalent attributes and classes
   - If \( A \equiv A', B \equiv B', A-B \equiv A'-A_1'-\ldots-A_m'-B' \) then include the longer path
     - as the length one path is subsumed by the longer path
     - as the longer one is more expressive with respect to cardinality
   - If \( A \equiv A', B \equiv B', A-A_1-\ldots-A_n-B \equiv A'-A_1'-\ldots-A_m'-B' \) then include both paths
     - as they represent different relationships to B

5. Equivalences between classes and attributes are included as relationships
   - again, prefer more expressive solution with respect to cardinality
Example: Class and Attribute Correspondences

- Class Correspondence

  \[ \text{Film} \equiv \text{Movie} \]

- Attribute Correspondences

  \[ \text{id} \equiv \text{movie_id} \]
  \[ \text{titel} \equiv \text{name} \]
  \[ \text{dir\_name} \equiv \text{director} \]
  \[ \text{studio} \equiv \text{s\_name} \]
Example: Relationship Path Correspondence 1

- Relationship Path Correspondence

\[ \text{dir\_name-Director-Directs-Film} \equiv \text{director-Movie} \]
Example: Relationship Path Correspondence 2

- Relationship Path Correspondence

\[ \text{studio-Directs-Film} \equiv \text{s\_name-Studio-Movie} \]
Creation of the Integrated Schema 1

- Integration Steps
  1. Rule 1: Equivalent classes **Film** and **Movie** are merged to **Film**. Attributes are either merged (*id, title*) or simply copied (*turnover, director, studio_id*).
  2. Rule 2: Classes without direct equivalent are included into the integrated schema (**Director, Directs, Studio**)
Correspondence

- \( \text{dir\_name-Director-Directs-Film} = \text{director-Movie} \)

Integration Steps

3. Rule 4a: The path \( \text{dir\_name-Director-Directs-Film} \) is included. The path \( \text{director-Movie} \) is left out as it is less expressive (allows only one director per movie).

4. Thus, \( \text{dir\_name} \) is kept and \( \text{director} \) removed.
Creation of the Integrated Schema 3

- Correspondence
  \[\text{studio-Directs-Film} = \text{s\_name-Studio-Movie}\]

- Integration Step
  5. Rule 4b: Both paths are included as both have a length > 1.
  - \textbf{Studio} and \texttt{studio} are not merged as they have a different relationship to the surrounding classes and might thus mean different things.

Source Schemata

- \texttt{Film}
  - id
  - title
  - genre
  - turnover
  - studio_id

- \texttt{Director}
  - person_id
  - dir_name
  - address
  - age

- \texttt{Directs}
  - film_id
  - dir_id
  - studio

- \texttt{Movie}
  - movie_id
  - name
  - studio_id
  - turnover
  - director

- \texttt{Studio}
  - id
  - s\_name
  - address
  - type

- Studio owns rights?
- The movie was shot in this studio?
Final Integrated Schema

Fulfills the schema integration goals

- **Completeness**: All elements of the source schemata covered
- **Correctness**: All data can be represented semantically correct
- **Minimality**: The integrated schema is minimal in respect to the number of relations and attributes
- **Understandability**: The schema is easy to understand
4. Data Translation

We are here

Target schema was available or has been created.

1. Find Correspondences

2. Translate Data

Source Schema

Logical Mapping

Target Schema

Source Data

Materialized Data in Target Schema

Translation Queries (Translation Program)
Query Generation

Goal: Derive suitable data translation queries (or programs) from the correspondences.

- Possible query types: SQL Select Into, SPARQL Construct, XSLT
- Example of a data translation query:

```
SELECT artPK AS pubID
  heading AS title
  null AS date
INTO PUBLICATION
FROM ARTICLE
```

- Challenges for more complex schemata
  - Correspondences are not isolated but embedded into context (tables, relationships)
  - Might require joining tables in order to overcome different levels of normalization
  - Might require combining data from multiple source tables (horizontal partitioning)
Normalized ➔ Denormalized

**ARTICLE**
- artPK
- title
- pages

**AUTHOR**
- artFK
- name

**PUBLICATION**
- pubID
- title
- date
- author

Naïve approach with one query per source table does not work.

```sql
SELECT artPK AS pubID, title AS title, null AS date, null AS author
INTO PUBLICATION
FROM ARTICLE
UNION
SELECT null AS pubID, null AS title, null AS date, name AS author
INTO PUBLICATION
FROM AUTHOR
```
Normalized → Denormalized

**ARTICLE**
- artPK
- title
- pages

**AUTHOR**
- artFK
- name

**PUBLICATION**
- pubID
- title
- date
- author

Suitable approach: Join tables using foreign key relationship.

```
SELECT artPK AS pubID, title AS title, null AS date, name AS author
INTO PUBLICATION
FROM ARTICLE, AUTHOR
WHERE ARTICLE.artPK = AUTHOR.artFK
```
INNER JOIN vs. OUTER JOIN

**ARTICLE**
- artPK
- title
- pages

**AUTHOR**
- artFK
- name

**PUBLICATION**
- pubID
- title
- date
- author

**Decision**: Do we want publications without author?

```sql
SELECT artPK AS pubID, title AS title, null AS date, name AS author
INTO PUBLICATION
FROM ARTICLE LEFT OUTER JOIN AUTHOR
ON ARTICLE.artPK = AUTHOR.artFK
```
Denormalized $\rightarrow$ Normalized

**PUBLICATION**
- title
- date
- author

**ARTICLE**
- artPK
- title
- pages

**AUTHOR**
- artFK
- name

```
SELECT SK(title) AS artPK
    title AS title
    null AS pages
INTO ARTICLE
FROM PUBLICATION

SELECT SK(title) AS artFK
    author AS name
INTO AUTHOR
FROM PUBLICATION
```

**SK()**: Skolem function used to generate unique keys from distinct values, e.g. hash function.
Horizontal Partitioning

Data for target table might be horizontally distributed over multiple source tables.

Correspondence 1: Professor.salary → Personnel.Sal
Correspondence 2: PayRate.HrRate * WorksOn.Hrs → Personnel.Sal
UNION the Salaries of Professors and Students

Correspondence 1: Professor.salary → Personnel.Sal
Correspondence 2: PayRate.HrRate * WorksOn.Hrs → Personnel.Sal

```
INSERT INTO Personal(Sal)

SELECT salary
FROM Professor

UNION

SELECT P.HrRate * W.hrs
FROM PayRate P, WorksOn W
WHERE P.Rank = W.ProjRank
```
Complete Algorithms for Generating Translation Queries

- **Relational Case**

- **XML Case**

- **MapForce**
  - implements another one which we will try out in the exercise
5. Schema Matching

Schema Matching: Automatically or semi-automatically discover correspondences between schemata.

- Automatically finding a complete high-quality mapping (= set of all correspondences) is difficult in many real-world cases
- In practice, schema matching is used to create candidate correspondences that are verified by domain experts afterwards
- Most schema matching methods focus on 1:1 correspondences
  - we restrict ourselves to 1:1 for now and speak about 1:n and n:1 later.
Schema Matching

1. Find Correspondences

Source Schema
- filmDB
- directors
- director
- personID
- name
- studio
- films
- film
- regieID
- filmID
- producer
- title

Target Schema
- movieDB
- studios
- studio
- directors
- director
- dirID
- dirname
- producers
- producer
- prodID
- name

Logical Mapping

Source Data

2. Translate Data

Translation Queries (Translation Program)

Materialized Data in Target Schema

We are here
Outline: Schema Matching

1. Challenges to Finding Correspondences

2. Schema Matching Methods
   1. Label-based Methods
   2. Instance-based Methods
   3. Structure-based Methods
   4. Combined Approaches

3. Generating Correspondences from the Similarity Matrix

4. Finding One-to-Many and Many-to-One Correspondences

5. Example Schema Matching System

6. Summary and Current Trends
5.1 Challenges to Finding Correspondences

1. Large schemata
   - >100 tables and >1000 attributes

2. Esoteric naming conventions and different languages
   - 4 character abbreviations: SPEY
   - city vs. ciudad vs. مدينة

3. Generic, automatically generated names
   - attribute1, attribute2, attribute3
     (was used as names for product features in Amazon API)

4. Semantic heterogeneity
   - synonyms, homonyms, …

5. Missing documentation
## Problem Space: Different Languages and Strange Names

### Personen

<table>
<thead>
<tr>
<th>Vorname</th>
<th>Nachname</th>
<th>male</th>
<th>female</th>

</tbody>
</table>
How do humans know?

- We recognize naming conventions and different languages
- use table context
- values look like first names and surnames
- values look similar
- if there is a first name, there is usually also a surname
- persons have first- and surnames
- man are persons

→ Recognizing these clues is hard for the computer
5.2. Schema Matching Methods

1. **Label-based Methods**: Rely on the names of schema elements
2. **Instance-based Methods**: Compare the actual data values
3. **Structure-based Methods**: Exploit the structure of the schema
4. **Combined Approaches**: Use combinations of above methods

5.2.1 Label-based Schema Matching Methods

- Given two schemata with the attribute (class) sets A and B
  - A={ID, Name, Vorname, Alter}, B={No, Name, First_name, Age}

- Approach
  1. Generate cross product of all attributes (classes) from A and B
  2. For each pair calculate the similarity of the attribute labels
     - using some similarity metric: Levenshtein, Jaccard, Soundex, etc.
  3. The most similar pairs are the matches

<table>
<thead>
<tr>
<th></th>
<th>ID</th>
<th>Name</th>
<th>Vorname</th>
<th>Alter</th>
</tr>
</thead>
<tbody>
<tr>
<td>No</td>
<td>0.8</td>
<td>0.6</td>
<td>0.4</td>
<td>0.4</td>
</tr>
<tr>
<td>Name</td>
<td>0.1</td>
<td>1.0</td>
<td>0.6</td>
<td>0.3</td>
</tr>
<tr>
<td>First_name</td>
<td>0.2</td>
<td>0.6</td>
<td>0.5</td>
<td>0.3</td>
</tr>
<tr>
<td>Age</td>
<td>0.4</td>
<td>0.3</td>
<td>0.2</td>
<td>0.7</td>
</tr>
</tbody>
</table>
Example Metric: Levenshtein

- Measures the dissimilarity of two strings
- Measures the **minimum number of edits** needed to transform one string into the other
- Allowed edit operations
  - **insert** a character into the string
  - **delete** a character from the string
  - **replace** one character with a different character
- **Examples**
  - `levensthein('table', 'cable') = 1` (1 substitution)
  - `levensthein('Chris Bizer', 'Bizer, Chris') = 11` (10 substitution, 1 insertion)
- Converting Levenshtein distance into a similarity

\[
sim_{Levenshtein} = 1 - \frac{Levenshtein\ nDist}{\max(|s_1|, |s_2|)}
\]
A Wide Range of Similarity Metrics Exists

See second lecture on Identity Resolution
Problems of Label-based Schema Matching

1. Semantic heterogeneity is not recognized
   - the labels of schema elements only partly capture their semantics
   - synonyms and homonyms

2. Problems with different naming conventions
   - Abbreviations: pers = person, dep = department
   - Combined terms and ordering: id_pers_dep vs. DepartmentPersonNumber
   - Different languages: city vs. ciudad vs. مدينة

   We need to apply **smart, domain-specific tweaks**:
   1. Preprocessing: Normalize labels in order to prepare them for matching
   2. Matching: Employ similarity metrics that fit the specifics of the schemata
Pre-Processing of Labels

- Case and Punctuation Normalization
  - ISBN, IsbN, and I.S.B.N → isbn

- Explanation Removal
  - GDP (as of 2014, US$) → gdp

- Stop Word Removal
  - in, at, of, and, ...
  - ex1:locatedIn → ex1:located

- Stemming
  - ex1:located, ex2:location → both stemmed to ‘located’
  - but: ex1:locationOf, ex2:locatedIn (Inverse Properties!)

- Tokenization
  - ex1:graduated_from_university → {graduated,from,university}
  - ex2:isGraduateFromUniversity → {is,Graduate,from,University}
  - tokens are then compared one-by-one using for instance Jaccard similarity
Use Linguistic Resources for Pre-Processing

- Translate labels into target language
  - ciudad and مدينة → city

- Expand known abbreviations or acronyms
  - loc → location, cust → customer
  - using a domain-specific list of abbreviations or acronyms

- Expand with synonyms
  - add cost to price, United States to USA
  - using a dictionary of synonyms

- Expand with hypernyms (is-a relationships)
  - expand product into book, dvd, cd

- Use taxonomy/ontology containing hypernyms for matching
  - similarity = closeness of concepts within taxonomy/ontology
Useful Resources for Pre-Processing

- Google Translate
  - recognizes languages and translates terms

- WordNet
  - provides synonyms and hypernyms for English words

- Wikipedia/DBpedia
  - provides synonyms, concept definitions, category system, cross-language links
  - see Paulheim: WikiMatch. 2012.
Given two schemata with the attribute sets A and B and

- all instances (records) of A and B or
- a sample of the instances of A and B

Approach

- determine correspondences between A and B by examining which attributes in A and B contain similar values
- as values often better capture the semantics of an attribute than its label

Types of instance-based methods

1. Attribute Recognizers
2. Value Overlap
3. Feature-based Methods
4. Duplicate-based Methods
Attribute Recognizers and Value Overlap

1. Attribute Recognizers
   - employ dictionaries, regexes or rules to recognize values of a specific attribute
     - Dictionaries fit attributes that only contain a relatively small set of values (e.g. age classification of movies (G, PG, PG-13, R), country names, US states
     - Regexes or rules fit attributes with regular values (e.g. area code – phone number).
   - similarity = fraction of the values of attribute B that match dictionary/rule of attribute A

2. Value Overlap
   - calculate the similarity of attribute A and B as the overlap of their values using the Jaccard similarity measure (or Generalized Jaccard):

\[
J(A, B) = \frac{|A \cap B|}{|A \cup B|}
\]
Given two schemata with the attribute sets A and B and instances of A and B

Approach
1. For each attribute calculate **interesting features** using the instance data, e.g.
   - attribute data type
   - average string length of attribute values
   - average maximal and minimal number of words
   - average, maximal and minimal value of numbers
   - standard derivation of numbers
   - does the attribute contain NULL values?
2. generate the cross product of all attributes from A and B
3. for each pair compare the similarity of the features
Example: Feature-based Matching

- Features: Attribute data type, average string length
  - Table1 = \{(ID, NUM, 1), (Name, STR, 6), (Loc, STR, 18)\}
  - Table1 = \{(Nr, NUM, 1), (Adresse, STR, 16), (Telefon, STR, 11)\}

- Similarity measure: Euclidean Distance (NUM=0, STR=1)

<table>
<thead>
<tr>
<th>ID</th>
<th>Name</th>
<th>Loc</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Müller</td>
<td>Danziger Str, Berlin</td>
</tr>
<tr>
<td>2</td>
<td>Meyer</td>
<td>Boxhagenerstr, Berlin</td>
</tr>
<tr>
<td>4</td>
<td>Schmidt</td>
<td>Turmstr, Köln</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Nr</th>
<th>Adresse</th>
<th>Telefon</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Seeweg, Berlin</td>
<td>030-3324566</td>
</tr>
<tr>
<td>3</td>
<td>Aalstr, Schwedt</td>
<td>0330-1247765</td>
</tr>
<tr>
<td>4</td>
<td>Rosenalleee, Kochel</td>
<td>0884-334621</td>
</tr>
</tbody>
</table>
Discussion: Feature-based Methods

1. Require decision which features to use
   - good features depend on the attribute data type and application domain

2. Require decision how to compare and combine values
   - e.g. cosine similarity, euclidian distance (of normalized values), …
   - different features likely require different weights

3. Similar attribute values do not always imply same semantics
   - phone number versus fax number
   - employee name versus customer name
Duplicate-based Methods

- Classical instance-based matching is **vertical**
  - Comparison of complete columns
  - ignores the relationships between instances

- **Duplicate-based matching is horizontal**
  1. Find (some) potential duplicates or use previous knowledge about duplicates
  2. Check which attribute values **closely match** in each duplicate
  3. Result: **Attribute correspondences per duplicate**
  4. Aggregate the attribute correspondences on duplicate-level into attribute correspondences on schema-level using **majority voting**.
**Example: Vote of Two Duplicates**

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
<th>E</th>
</tr>
</thead>
<tbody>
<tr>
<td>Max</td>
<td>Michel</td>
<td>m</td>
<td>601-4839204</td>
<td>601-4839204</td>
</tr>
<tr>
<td>Sam</td>
<td>Adams</td>
<td>m</td>
<td>541-8127100</td>
<td>541-8121164</td>
</tr>
</tbody>
</table>

- Vote of the two duplicates:

  - Resulting schema-level correspondences:
    - $B \equiv B'$, $E \equiv E'$, $A \equiv F$
Using Duplicates for Cross-Language Infobox Matching

Source: Felix Naumann, ICIQ 2012 Talk
Discussion: Duplicate-based Methods

- Can correctly distinguish very similar attributes
  - Telephone number <> fax number, Surname<>Maiden name

- Work well if duplicates are known or easy to find
  - owl:sameAs statements in LOD cloud
  - shared IDs like ISBN or GenID

- Does not work well if identity resolution is noisy
  - e.g. persons or cities of which only the name is known
5.2.3 Structure-based Schema Matching Methods

- Addresses the following problem:

  ![Diagram showing attribute matching between employee, jobholder, buyer, and customer]

- Attribute-Attribute-Matching
  - Instance-based: Values of all attributes rather similar
  - Label-based: Labels of all attributes rather similar
  - All matchings are about equally good 😁
Better approach: Exploit the Attribute Context

- Attributes that co-occur in one relation often (but not always) also co-occur in other relations.
Approach: Spread Similarity to Neighbors

- Idea: High similarity of neighboring attributes and/or name of relation increases similarity of attribute pair.
- Base similarities: Label-based and/or instance-based matching.
- Simple calculation: Weight attribute similarity with average similarity of all other attributes in same relation and similarity of relation names.
- Alternative calculation: Similarity Flooding algorithm (see references).
5.2.4 Combined Approaches

- Hybrid Approaches
  - integrate different clues into single similarity function
  - clues: labels, structure, instance data

- Ensembles
  1. apply different base matchers
  2. combine their results
**Example of the Need to Exploit Multiple Types of Clues**

<table>
<thead>
<tr>
<th>listed-price</th>
<th>contact-name</th>
<th>contact-phone</th>
<th>office</th>
<th>comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>$250K</td>
<td>James Smith</td>
<td>(305) 729 0831</td>
<td>(305) 616 1822</td>
<td>Fantastic house</td>
</tr>
<tr>
<td>$320K</td>
<td>Mike Doan</td>
<td>(617) 253 1429</td>
<td>(617) 112 2315</td>
<td>Great location</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>homes.com</th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>sold-at</td>
<td>contact-agent</td>
<td>extra-info</td>
<td></td>
<td></td>
</tr>
<tr>
<td>$350K</td>
<td>(206) 634 9435</td>
<td>Beautiful yard</td>
<td></td>
<td></td>
</tr>
<tr>
<td>$230K</td>
<td>(617) 335 4243</td>
<td>Close to Seattle</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- **If we use only labels**
  - contact-agent matches either contact-name or contact-phone

- **If we use only data values**
  - contact-agent matches either contact-phone or office

- **If we use both labels and data values**
  - contact-agent matches contact-phone
How to Combine the Predictions of Multiple Matchers?

- **Average combiner**: trusts all matchers the same

- **Maximum combiner**: when we trust a strong signal from a single matcher.

- **Minimum combiner**: when we want to be more conservative and require high values from all matchers

- **Weighted-sum combiner**
  - assign a weight to each matcher according to its quality
  - you may learn the weights using
    - known correspondences as training data
    - linear/logistic regression or decision tree learning algorithms
    - we will cover learning weights in detail in chapter on identity resolution
5.3 Generating Correspondences from the Similarity Matrix

Input: Matrix containing attribute similarities
Output: Set of correspondences

Local Single Attribute Strategies:

1. Thresholding
   - all attribute pairs with sim above a threshold are returned as correspondences
   - domain expert checks correspondences afterwards and selects the right ones

2. TopK
   - give domain expert TopK correspondences for each attribute

3. Top1
   - directly return the best match as correspondence
   - very optimistic, errors might frustrate domain expert
Alternative: Global Matching

- Looking at the complete mapping (all correct correspondences between A and B) gives us the additional restriction that one attribute in A should only be matched to one attribute in B.

- **Goal of Global Matching**
  - Find optimal set of disjunct correspondences
  - avoid correspondence pairs of the form $A \equiv C$ and $B \equiv C$

- **Approach:**
  - find set of bipartite pairs with the maximal sum of their similarity values

- **Example:**
  - $A \equiv D$ and $B \equiv C$ have the maximal sum of their similarity values
  - Ignores that $\text{sim}(A,C) = 1$
Alternative: Stable Marriage

- Elements of A = women, elements of B = men
- Sim(i,j) = degree to which Aᵢ and Bⱼ desire each other
- Goal: Find a stable match combination between men and women
- A match combination would be unstable if
  - there are two couples Aᵢ = Bⱼ and Aₖ = Bₙ such that Aᵢ and Bₙ want to be with each other, i.e., Sim(i,n) > Sim(i,j) and Sim(i,n) > Sim(k,l)
- Algorithm to find stable marriages
  - Let match={}
  - Repeat
    - Let (i,j) be the highest value in Sim such that Aᵢ and Bⱼ are not in match
    - Add Aᵢ = Bⱼ to match
- Example: A = C and B = D form a stable marriage
Up till now all methods only looked for 1:1 correspondences

But real-world setting might require n:1 and 1:n or even n:m correspondences

Question:
- How to combine values?
- Lots of functions possible.

Problem:
- Should we test $1.2 \times A + 2 \times B - 32 \equiv C$
- … unlimited search space!

n:1 Correspondence
- Vorname \(\rightarrow\) concat() \(\rightarrow\) Name
- Nachname

1:n Correspondence
- Name \(\rightarrow\) extract() \(\rightarrow\) Vorname
- Name \(\rightarrow\) extract() \(\rightarrow\) Nachname

m:n Correspondence
- Name \(\rightarrow\) extract() \(\rightarrow\) concat() \(\rightarrow\) First name
- Title \(\rightarrow\) extract() \(\rightarrow\) Last name
Search for Complex Correspondences

- Employs specialized searchers:
  - text searcher: uses only concatenations of columns
  - numeric searcher: uses only basic arithmetic expressions
  - date searcher: tries combination of numbers into dd/mm/yyyy pattern

- Key challenge: Control the search.
  - start searching for 1:1 correspondences
  - add additional attributes one by one to sets
  - consider only top k candidates at every level of the search
  - termination based on diminishing returns
An Example: Text Searcher

---

**Mediated-schema**

<table>
<thead>
<tr>
<th>price</th>
<th>num-baths</th>
<th>address</th>
</tr>
</thead>
<tbody>
<tr>
<td>listed-price</td>
<td>agent-id</td>
<td>full-baths</td>
</tr>
<tr>
<td>320K</td>
<td>532a</td>
<td>2</td>
</tr>
<tr>
<td>240K</td>
<td>115c</td>
<td>1</td>
</tr>
</tbody>
</table>

- **Best match candidates for address**
  - (agent-id,0.7), (concat(agent-id,city),0.75), (concat(city,zipcode),0.9)
5.5. Example Matching System: COMA V3.0

Developed by Database Group at University of Leipzig since 2002
- provides wide variety of matchers (label, instance, structure, hybrid)
- provides user interface for editing correspondences.
- provides data translation based on the correspondences.

http://dbs.uni-leipzig.de/de/Research/coma.html
5.6. Summary

- Schema Matching is an active research area with lots of approaches
  - yearly competition: Ontology Alignment Evaluation Initiative (OAEI)

- Quality of found correspondences depends on difficulty of problem
  - many approaches work fine for toy problems, but fail for larger schemas
  - hardly any commercial implementations of the methods

- Thus it is essential to **keep the domain expert in the loop**.
  - Active Learning
    - learn from user feedback while searching for correspondences
  - Crowd Sourcing
    - mechanical turk
    - click log analysis of query results
    - DBpedia Mapping Wiki
  - Spread the manual integration effort over time
    - pay-as-you-go integration in data spaces (aka data lakes)
The Dataspace Vision

Alternative to classic data integration systems in order to cope with growing number of data sources.

Properties of dataspaces

- may contain any kind of data (structured, semi-structured, unstructured)
- require no upfront investment into a global schema
- provide for data-coexistence
- provide give best effort answers to queries
- rely on pay-as-you-go data integration

6. Schema Heterogeneity on the Web

1. Role of Standards
   1. RDFa/Microdata/Microformats
   2. Linked Data

2. Self-Descriptive Data on the Web
For publishing data on the Web, various communities try to avoid schema-level heterogeneity by agreeing on standard schemata (also called vocabularies or ontologies).

- **Schema.org**
  - 600+ Types: Event, local business, product, review, person, place, …

- **Open Graph Protocol**
  - 25 Types: Event, product, place, website, book, profile, article

- **Linked Data**
  - various widely used vocabularies
  - FOAF, SKOS, Music Ontology, …
Vocabularies used together with the RDFa Syntax

Number of Websites (PLDs)

- 100,000  200,000  300,000  400,000  500,000  600,000

<table>
<thead>
<tr>
<th>Vocabulary</th>
<th>Websites</th>
</tr>

Vocabularies in the LOD Cloud

Data sources **mix terms** from commonly used and proprietary vocabularies.

- **Idea**
  - Use common, easy-to-understand vocabularies wherever possible.
  - Define proprietary vocabularies terms only if no common terms exist.

- **LOD Cloud Statistics 2014**
  - 378 (58.24%) proprietary vocabularies, 271 (41.76%) are non-proprietary

- **Common Vocabularies**

<table>
<thead>
<tr>
<th>Vocabulary</th>
<th>Number of Datasets</th>
</tr>
</thead>
<tbody>
<tr>
<td>foaf</td>
<td>701 (69.13%)</td>
</tr>
<tr>
<td>dcterms</td>
<td>568 (56.02%)</td>
</tr>
<tr>
<td>sioc</td>
<td>179 (17.65%)</td>
</tr>
<tr>
<td>skos</td>
<td>143 (14.10%)</td>
</tr>
<tr>
<td>void</td>
<td>137 (13.51%)</td>
</tr>
<tr>
<td>cube</td>
<td>114 (11.24%)</td>
</tr>
</tbody>
</table>

6.2 Self-Descriptive Data

Data sources in the LOD context try to increase the usefulness of their data and ease data integration by making it self-descriptive.

Aspects of self-descriptiveness

1. Reuse terms from common vocabularies / ontologies
2. Enable clients to retrieve the schema
3. Properly document terms
4. Publish correspondences on the Web
5. Provide provenance metadata
6. Provide licensing metadata
Reuse Terms from Common Vocabularies

1. Common Vocabularies
   - **Friend-of-a-Friend** for describing people and their social network
   - **SIOC** for describing forums and blogs
   - **SKOS** for representing topic taxonomies
   - **Organization Ontology** for describing the structure of organizations
   - **GoodRelations** provides terms for describing products and business entities
   - **Music Ontology** for describing artists, albums, and performances
   - **Review Vocabulary** provides terms for representing reviews

2. Common sources of identifiers (URIs) for real world objects
   - **LinkedGeoData** and **Geonames** locations
   - **GenelID** and **UniProt** life science identifiers
   - **DBpedia** and **Wikidata** wide range of things
Enable Clients to Retrieve the Schema

Clients can resolve the URIs that identify vocabulary terms in order to get their RDFS or OWL definitions.

Some data on the Web

```
<http://richard.cyganiak.de/foaf.rdf#cygri>
    foaf:name "Richard Cyganiak" ;
    rdf:type <http://xmlns.com/foaf/0.1/Person> .
```

Resolve unknown term

```
http://xmlns.com/foaf/0.1/Person
```

RDFS or OWL definition

```
<http://xmlns.com/foaf/0.1/Person>
    rdf:type owl:Class ;
    rdfs:label "Person";
    rdfs:subClassOf <http://xmlns.com/foaf/0.1/Agent> ;
    rdfs:subClassOf <http://xmlns.com/wordnet/1.6/Agent> .
```
The documentation of a vocabulary is published on the Web in machine-readable form and can be used as a clue for schema matching.

- **Name of a vocabulary term**
  - `ex1:name rdfs:label "A person's name"@en`.
  - `ex2:hasName rdfs:label "The name of a person"@en`.
  - `ex2:hasName rdfs:label "Der Name einer Person"@de`.

- **Additional description of the term**
  - `ex1:name rdfs:comment "Usually the family name"@en`.
  - `ex2:name rdfs:comment
     "Usual order: family name, given name"@en`.
Publish Correspondences on the Web

Vocabularies are (partly) connected via vocabulary links.

Vocabulary Link

```
<http://dbpedia.org/ontology/Person>
owl:equivalentClass
<http://xmlns.com/foaf/0.1/Person> .
```

- Terms for representing correspondences
  - owl:equivalentClass, owl:equivalentProperty,
  - rdfs:subClassOf, rdfs:subPropertyOf
  - skos:broadMatch, skos:narrowMatch
Deployment of Vocabulary Links

Vocabulary links:
Vocabularies referencing "foaf" (119)

Vocabularies referenced by "mo" (17)

Source: Linked Open Vocabularies, https://lov.linkeddata.es/dataset/lov/
Summary: Structuredness and Standard Conformance

Structuredness of Web Content

- DB Dump
- Classic HTML
- LOD
- RDFa

Schema Standard Conformance
